1. Introduction

1.1. Background to the Problem

Governments have been undergoing digital transformation as a means of reforming their public sector in the context of using digital services or e-government services to improve accessibility, efficiency, transparency and engagement with their citizens. The United Nations (2022) shows us that digital government can strengthen the connection between citizens and essential public services. However, the benefits of digital government does not depend only on the adoption of these e-government services but also the continued use or continuance of these e-gov services over time. In many settings, e-gov services often experience a drop in usage after launch, this limits the return on investment and it also encourages the return to in person and paper based processes.

Guyana has gone far in terms of its digital transformation in recent years, with agencies introducing e-gov services that are to expand access to public services. The Guyana Revenue Authority (GRA) ‘Padna’ App is a prime example of one of those initiatives and forms part of the country’s upcoming digital tax ecosystem. These e-gov services are seen as convenient alternatives as of right now. National assessments report both structural and social barriers that can affect the continued use of these e-gov services especially across coastal, rural and hinterland

communities (UNDP, 2023; Guyana REDD+ Investment Fund, 2022). These conditions tell us that the challenge at the center of this for Guyana is not the releasing of these e-gov services but it is in fact the continued use of said services in a context of uneven connectivity, variable digital literacy and persistent trust and privacy concerns.

The ‘Padna’ App is a mobile and web based platform that was designed to streamline tax related transactions and interactions between taxpayers and GRA. It gives citizens access to services such as tax filing, compliance monitoring, account information retrieval, payment verification and notifications related to tax obligations. This e-gov services reduces the need to go to a GRA office in person while also putting different tax services into one single digital channel as opposed to going in person and having to join multiple lines, this saves citizens time, provides convenience and reduces the need for paper based processing. From a strategic perspective, the continued use of the ‘Padna’ App can improve efficiency, reduce errors and increase transparency, which can strengthen compliance outcomes (Susanto & Suryana, 2022). For Guyana where the tax base has to be able to support rapid economic change and expanding demand for public services, continued use of these e-gov services is necessary.

Despite the benefits that the ‘Padna’ App (among other e-gov services) intend to give the citizens, evidence from information systems research shows us that initial adoption does not

guarantee the continued use of e-gov services. Citizens might stop using e-gov services when their experience does not meet expectations, when there are usability issues or when the perceived risk is greater than the value (Bhattacharjee, 2001). In e-gov services, trust and perceived security become one of the most important factors because citizens have to share sensitive personal and financial information and because citizens evaluate the service through their perceptions of the public institution responsible. As a result, the continued use is usually a combination of user experience (UX), perceived value and any other contextual conditions at the time.

Guyana is a distinctive environment for examining continuance challenges. UNDP (2023) shows us disparities in digital access across regions, including limitations in broadband availability, device access and digital literacy. The Guyana REDD+ Investment Fund (2022) also shows issues that can take away from continued use, including limited support structures, uneven awareness and trust and privacy concerns. These factors can contribute to e-gov services existing but not achieving long-term use which will affect the impact of digital transformation.

This study will go after the problem of limited continued use of e-government services in Guyana by using the GRA Padma App as a focused case where we will look at the barriers and the drivers of continuance. The study will use the Expectation–Confirmation Model (ECM) as

the core post-adoption framework and uses supporting constructs from UTAUT2, such as habit, social influence and facilitating conditions and trust and perceived security. This model will let us use evidence based explanations to tell us why continued use is limited and what we can do to help increase continued use of egov services.

Statement of the Problem

The Government of Guyana has invested in digital platforms to modernize public services and improve access for its citizens. E-gov services such as the GRA 'Padna' App should reduce burden on both GRA and citizens, increase convenience and strengthen efficiency in tax transactions. In real life, the value given to citizens from e-gov services, is constrained when those citizens choose to not continue using those e-gov services after initial exposure to them or when they use those e-gov services inconsistently and return to traditional non-digital channels. This gap between availability and continued use limits the efficiency citizens can gain and reduces the reliability of digital channels and weakens the policy objectives that the government hopes to achieve with their digital transformation.

Studies tell us that continuance rates are low after adoption when the e-gov services have unsatisfactory experiences such as, technical issues, low perceived usefulness, weak usability and trust and privacy concerns (Bhattacharjee, 2001). In terms of e-gov, these challenges become

worse because of the perceived risk and institutional trust shape willingness to work digitally especially when transactions involve sensitive information (Bélanger & Carter, 2008). In Guyana, assessments done on the country's readiness tell us that constraints such as inconsistent internet access, limited infrastructure in hinterland areas, digital literacy and limited confidence in digital public services, can undermine the continuance of e-gov services(UNDP, 2023).

The conditions in Guyana can suggest that there will be limited continued use of e-gov services and would present a systematic barrier to said e-gov services in Guyana, no empirical studies have looked at the determinants of continued use and non continued use for GRA's Padna App specifically which is a major service for Guyanese citizens, this creates a critical evidence gap for policy makers and service UI/UX designers because improving continued use of these e-gov services requires a clear understanding of the factors that encourage the continued use as well as the factors that discourage continued use of e-gov services. So the problem addresses by this study is the lack of empirical evidence telling us why there is limited use of the GRA Padna App as a contribution towards reaching the continued use of e-gov services in Guyana.

1.2. Research Question and Objectives

1.2.1. Questions

- What are the main factors that explain the limited continued use of the GRA Padna App among Guyanese taxpayers?

1.2.2. Objectives

Main Objective

1. Using the Expectation - Confirmation Model in combination with constructs from UTAUT2 to examine why Guyanese citizens stopped using the Padna app

Secondary Objectives

- Identifying how constructs like confirmation, perceived usefulness and satisfaction affect the continued use and potential discontinuance of the Padna app
- Examine how routine and people surrounding Padna users influence the continued use of the Padna app
- Verifying if setup improves or diminish continued app usage
- Providing advice for GRA to improve user retention with Padna App

1.3. Significance of the Project

Academic Significance

- This research will contribute to the field of Information Systems research and improve our understanding of digital systems by examining issues in the Caribbean e-government. By using models like ECM, UTAUT2, and trust construct, we can gain insight into how and why people use e-government services after rollout.

- **Policy and Industry Significance**

The results of this study could help GRA and relevant stakeholders improve the quality of the Padna app. The benefits aren't only limited to GRA as the results could lead to broader digital changes by providing insight into real world issues that stop people from using apps.

- **Societal Significance**

- As stated above, by identifying what interferes with the continued usage of an app GRA could make the Padna app better which could lead to a butterfly effect with e-government services making things easier for Guyanese citizens. On top of that by making the Padna app reliable and building trust with citizens, other Guyanese e-government apps could see some success as well.

2. Literature Review

2.1. Overview

This literature review will look at theories and past findings about why people stop using e-government apps after using them for a short period of time. More specifically earlier works on what keeps users engaged and what pushes them away will be explored. With this exploration the plan is the aim of gaining an understanding of why Guyanese people do not continuously use e-government services with a focus on the GRA Padna App. In the literature we will come across models like the Expectation Confirmation Model (ECM), which will help to show if experiences live up to expectations. Another model would be the Unified Theory of Acceptance and Use of Technology 2 (UTAUT2) which contains constructs like routine, peer pressure and support access.

2.2. Continued use and discontinuance in e-government

Digital government projects often claim they will make administration faster, more open, less effortful for people to reach services. Still, just launching a service does not mean people keep using it. Multiple e-government tools experience a drop in users over a period of time. Recent studies have shown that user retention isn't simply achieved by releasing a shiny new app; it depends heavily on continuous usage by the public across different levels of connectivity, skills, and trust in institutions (Haug et al., 2023; United Nations Department of Economic and Social

Affairs, 2024).

A person thinking to keep using an egov service is not just their first impressions. The person needs to test it out and see how the service works and consider their experience. If the user does stop using the e-government service its most likely a result of frustration which may have been triggered by annoyance, distrust or poor access. For a user to sustain usage of an e-government it would depend on personal benefit, ease of use and real life hurdles compared to the app just running fine.

One big gap in current research is in how the continued use of e-government services are tracked, which tends to be through stated intent instead of actual actions. A person can say whatever they like but this doesn't guarantee that they will follow through with it, which makes this approach extremely optimistic. Continued usage of an e-government service is usually impacted by external factors like an unstable internet connection, lack of devices or poor digital literacy. If a user is impacted by factors like this then even great design and user satisfaction will fall to the wayside (Kala et al., 2024).

2.3. Expectation–Confirmation Model as a core framework

The Expectation–Confirmation Model (Bhattacharjee, 2001) will be used to explain what drives users to continue using something after initially adopting it. Instead of focusing on the user's first

impressions it focuses on real world usage in terms of achieving or missing the user's predictions. When a system performs the way a user expects there is a higher chance they will stick with said system/app. This is because the match between what the user expected and the actual performance was met, which in turn leads to satisfaction. This satisfaction in turn influences whether they continue using the app. What users think about an app's utility will also influence their perceived usefulness. Unlike earlier models, this model examines continued use as an evolving process. Pulling from Oliver's (1980) work in consumer psychology, it uses those ideas specifically for digital tools and platforms. At its core, the model emphasizes reflection rather than just reaction.

The Expectation Confirmation Model (ECM) (Bhattacharjee, 2001) is one of the most influential frameworks for examining post adoption behavior. ECM proposes that a user's intention to continue using something is affected by confirmation of expectations through their experience, perceived, how useful users think the service will be to them and using satisfaction to evaluate how users feel after using a service. ECM is rooted in the expectation confirmation theory in consumer behavior and reframes said theory for the context of information systems where post adoption learning and reassessment are vital.

Likewise, government app research has indicated that service quality may indirectly influence continuance through ECM mechanisms. Specifically, Mao et al. (2023) have found that continuance intention is enhanced by government app service quality at the holistic level, by

confirming expectations, perceived usefulness and satisfaction. This indicates that users' retention depends on the perception of performance consistent with their expectations and their continued benefits from using the app.

Research shows that the quality of a service can indirectly influence whether users continue to use it by using ECM. Mao et al. (2023) reported that the quality of a government app service increases continuance intention via expectation confirmation, perceived usefulness and satisfaction, which implies that the continued use of an app depends on whether the app matches the user's expectations and whether users believe that continuing to use said app would benefit them over time.

Though ECM is a great model for this paper, weaknesses appear often in published work. One issue is that a lot of the research depends on the data collected at a single point making it hard to trace cause and effect patterns or track shifts in ongoing usage attitudes over time.

The ECM model is strong but the research has issues. A lot of research uses surveys that they only take once and it makes it hard to see people's thoughts about using an e gov service change over time. Most studies need people telling them what they think which can be biased even when

researchers try to control it. Confirmation is also measured in a very narrow way because even though please might not have clear expectations especially if they are using a service because it is their one or few choice.(Bhattacharjee, 2001; Luo et al., 2024; Mao et al., 2023).

2.4. Extending post-adoption explanation beyond ECM

2.4.1. Service quality and IS success perspectives

Lately studies on e-government continuation mix ECM with service quality and information systems effectiveness. What shapes assessments after adoption is closely to how well systems operate and services reach users. Putting TAM with the Information Systems Success Model, Kala et al. (2024) tells us that people being happy based on system quality, clear information and strong service support. That sense of fulfillment will make them want to keep using platforms and levels of public confidence.

Kala et al. (2024) used TAM and the Information Systems Success Model and found that that information quality, service quality and system quality influences user satisfaction, which predicts continuance intention and citizen trust. Kala et al. (2024) also found that things like the differences in residential status which proves that in the infrastructural and demographic context can affect continued use.

2.5. Habit, social influence and facilitating conditions (UTAUT2)

UTAUT2 adds ideas that help explain how people keep using a system based on routine and situation. Habit means using a system becomes automatic when it is used often. However, government services are usually used only once in a while, such as when paying taxes, so habits do not form easily. Because of this, people may stop using these services unless they are designed to be simple, supported with reminders, and easy to access (Limayem et al., 2007; Venkatesh et al., 2012).

Team members or organizations advocating for specific actions often see compliance as a result. Social influence is the main factor no matter if it is the expectations at the workplace or the words from experts. The presence of the readiness scales peacefully up to the readiness state operated by the particular systems. The findings show that these conditions are very important when people encounter unequal infrastructure and capacity, and thus they are necessary for the sustainable usage in developing contexts (Venkatesh et al., 2012; Ain et al., 2016; Kala et al., 2024).

A common problem in the literature is that UTAUT2 is often tested to explain why people start using a system and then reused to explain continued use without fully considering what happens

after people gain experience, how often the service is used, or the fact that some government services are almost mandatory. This suggests that UTAUT2 works best when used alongside ECM, rather than on its own, and should play a supporting role instead of being the main framework (Venkatesh et al., 2012; Bhattacharjee, 2001).

2.6. Trust, perceived risk and legitimacy in e-government continuance

Although commonly overlooked, trust plays a central role in whether digital governance works, people share sensitive details only when they feel certain about how those are managed. In e gov services, people often think about faith in the government behind the system, how much they would need to rely on the tool and the assurance that data will stay accurate. (Carter & Bélanger, 2005; Bélanger & Carter, 2008).

People do not just want to know a platform works, they come back when they believe it will keep working. From past studies we can see that trust is not just on its own but it also helps with validation and usability. Looking at Luo and colleagues in 2024, we can see that trust is the main reason people kept using egov services.

For e gov services, trust comes from how risky people think they are and how protected they think their data will be. We know that the more open and fair people see egov services the more they trust them. This is especially important for things like tax services where people care about whether the system is legitimate (Dwivedi et al., 2017; Mushi et al., 2024).

2.7. Digital divide in developing countries

Even down to the best online government services may not be used much if people face basic barriers. From past studies we can say that digital changes in government can make barriers worse because not everyone has good internet or the skills to use it so some people can not fully benefit (Haug et al., 2023). We can say that we need some sort of digital skills to keep using e-government but many studies do not include them (Ibrahim, 2025).

This research is very important for Guyana. Reports will tell us that the government is working to improve internet access in remote areas since where people live affects how well they can use and keep using services (UNDP Guyana, 2023; Guyana REDD+ Investment Fund, 2022). At the same time different sources give different numbers for internet access so we can not assume everyone has the same quality or the same level of access. This shows the need to study what really helps people keep using e-government services in Guyana (UNDP Guyana, 2023; United Nations Department of Economic and Social Affairs, 2024).

2.8. Synthesis and research gap

With all the past research we can say that ECM's main idea is correct, people will continue using egov services if it meets their expectations and it is useful and they are satisfied with it. Recent studies also show that trust and service quality can make these effects stronger (Luo et al., 2024; Mao et al., 2023; Kala et al., 2024). However, there are still some gaps that this study aims to address:

Problem gap: Research talks about continued use as a good thing but does not look closely at why people stop using services in certain government contexts. This study focuses directly on

the problem of limited continued use, which is key to how well e-government actually works (Haug et al., 2023; Bhattacharjee, 2001).

Context gap: Reference to the Caribbean and Guyana The existing data is mostly concentrated in the regions of Asia and Middle East whereas the Caribbean does not have a lot of studies available with Guyana being even less.

Model gap: Some studies use ECM with trust and service quality but not a lot look at ECM together with certain UTAUT2 factors like whether people have the tools and habits to use services especially in developing countries where services aren't used often (Kala et al., 2024; Limayem et al., 2007; Venkatesh et al., 2012).

Practical gap for Padna: There is no research that looks at why people keep using or stop using the GRA Padna App. This leaves a clear gap in knowledge for improving policies and the system, especially since tax services are sensitive and require people to keep using digital tools properly (Bélanger & Carter, 2008; Susanto & Suryana, 2022).

This study will contribute by explaining why there is limited continued use of Guyana's e-government services, using Padna as its case to address broader discontinuance barriers to e-government services by using a context sensitive post adoption model to explain the limited continuance.

3. Research Design and Methodology

3.1. Overview

This chapter explains how the study was done to find out why people don't keep using the GRA Padna App, showing the challenges of continuing e-government services in Guyana. It covers the research approach and design, how the model and survey were created, who took part and how data was collected, why the analysis methods were chosen, and also discusses ethics and study limitations.

3.2. Research approach, philosophy and design

3.2.1. Research approach

This study is based on a quantitative approach. A quantitative design is appropriate for this study because the research question aims to quantify the relationships between previously well-defined constructs (e.g. confirmation, perceived usefulness, satisfaction, trust, habit, social influence and facilitating conditions) and to give meaning to the explanation of continuance and, inversely, discontinued use (Bhattacharjee, 2001; Venkatesh et al., 2012).

Earlier studies on e-government use surveys and methods with statistics and they use structural equation modelling to see why people keep using services and how different reasons are connected to each other. (Luo et al., 2024; Mao et al., 2023; Napitupulu et al., 2024). These studies show that using a quantitative approach is a good way to study how people continue using digital government services.

3.3. Research philosophy and reasoning

We will use a positivist approach for this study. Positivism tells us that social things can be measured objectively with reliable tools and that the bridges between different factors we can test if we use statistics. This fits the study because it uses well established concepts from information systems research and focuses on testing hypotheses.

We use deductive logic. It commences by identifying extant theory, developing hypotheses predicated on the ECM, and particular UTAUT2 and trust factors, and then evaluating these hypotheses by means of collected data (Bhattacharjee, 2001; Venkatesh et al., 2012).

3.4. Research design

We will use a survey which collects data at one point in time. This approach is common in research on why people keep using a service, using established theories to explain it (Bhattacharjee, 2001; Mao et al., 2023). Even though studies over time can show changes, a one time survey works well here because there is no previous data on Padma use.

3.5. Conceptual model and instrument development

3.5.1. Conceptual model

This research evaluates a combined framework in which the ECM forms the central post-use foundation while certain UTAUT2 elements alongside trust and perceived safety contribute situational and conduct related support specific to digital government platforms.

Built into this extended version are aspects like routine, environment, habit, peer impact and enabling factors from UTAUT2 informed by Venkatesh et al (2012) and Limayem et al (2007). Trust serves to address the greater sensitivity to risk of government systems that involve the management of personal and financial information (Bélanger & Carter, 2008; Carter & Bélanger, 2005).

3.5.2. Data capture instrument

Data will be captured using a structured questionnaire comprising multi-item measures for each construct. From tested scales, some items will be used to back up ideas while lining them alongside earlier findings. Though drawn from past papers, ECM elements take shape here via Bhattacharjee's 2001 framework. Instead of building fresh, habit, peer pressure, and ease-of-use bits arrive by way of UTAUT2 plus select writings around that theme, such as Venkatesh and team in 2012 or Limayem a few years prior. When trust steps into view, pieces emerge not from guesswork but solid studies on digital government confidence, where systems and tech each hold weight, much like Bélanger with Carter did in 2008 and again before that in 2005.

Answers will be quantified through a Likert-type scale (e.g. five-point or seven-point). To quantify perceptions and intentions needed for variable modelling in continuance research, Likert scales are commonly used (Mao et al., 2023; Luo et al., 2024). Additionally we will add some demographic and usage-context questions (e.g. region, age range, previous Padma usage frequency, accessibility) to describe the sample and facilitate the interpretation of enabling conditions.

3.5.3. Pilot testing

A pilot test will be done on a small number of users who meet the inclusion criteria to assess whether the items are understandable, the approximate time needed to complete the survey, and whether there are any ambiguities (Hair et al., 2006). The design of the questionnaire should be checked before the main survey to ensure that the questions are not misinterpreted, and that the survey does not take too long to complete (Fink et al., 1983).

3.5.4. Target population

The target population is taxpayers who have used the GRA Padna App in Guyana since users are in the best position to evaluate the system used (Nemasannek, 1972). Additionally, Taxpayers are chosen because they are the primary users of the system. Therefore, they are the best individuals to collect data regarding their experiences.

3.5.5. Target Population

Who could/could not be included

Who could be included?

- People who are 18 years or older
- People who reside in Guyana
- People who have accessed the Padna App at least once to complete any form of tax preparation or submission

Who could not be included?

- Anyone who has never accessed the Padna App
- Anyone who is younger than 18 years old
- Submissions that have a large amount of missing data or failed attention checks where used

3.5.6. Strategy of sampling and reasons for its use/sample size.

The most likely method to be used for selecting who will be asked to participate (sampling strategy). Rationale which explains why the number of people chosen to be included in the study is right for answering the research questions. How people taking part are going to be chosen; likely in this case, using a self-selection or advertising/population approach. Also, why this number of participants is being sought for the study rather than fewer or more people.

We will determine the sample size by conducting a power analysis rather than relying on rule-of-thumb thresholds. Power analysis is recommended to establish minimum sample sizes based on characteristics of the model and expected effects, and to enhance statistical conclusion validity (Cohen, 1992; Faul et al., 2009). We will perform power calculations using GPower, a popular tool for regression-based power analysis that can determine minimum sample sizes for models estimated by variance-based methods (Faul et al., 2009). We will then aim to obtain a sample size over and above this minimum power threshold to ensure that the estimates are stable and to provide descriptives for relevant subgroups when possible.

3.6. The Data collection strategy and procedures

3.6.1. Data collection method

Data will be collected through an online questionnaire via a suitable medium (e.g. social media, professional network groups, taxpayer advocacy groups, or institutional channels where permissible). Online questionnaires are appropriate since Padna is a digital solution and users likely have internet access at least intermittently.. Online administration also provides wide geographical coverage and is a cost-effective method of gathering information.

3.6.2. The timings and setting

Data collection will occur over a defined period sufficient to obtain an adequate sample. The survey will be self-administered in participants' natural settings, reflecting real-world usage contexts. The start section of the survey will give details about the research. It checks if you

qualify by asking a few questions. Following that comes a note where agreement to join is confirmed.

3.6.3. Procedures for quality control

The questionnaire will be have explicit guidance and may have an attention check question to ensure data accuracy. To protect privacy, no identifiable tax information such as TINs will be requested in the questionnaire. Responses will be sent off to an analysis software.

3.7. Data analysis strategy and justification

3.7.1. Analytical technique

The study will use Partial Least Squares Structural Equation Modelling (PLS-SEM) to analyse the survey data and verify whether the proposed relationships in the model are supported.

PLS-SEM is a good choice because it is designed for studies that focus on predicting outcomes and that include several hidden factors connected through multiple relationships. It also works

well when survey data are not perfectly normally distributed, which is common in behavioural research (Hair et al., 2017; Hair & Alamer, 2022). Recent research guidelines also recommend PLS-SEM for practical models that aim to explain results and test how well they predict behaviour (Ringle et al., 2023).

3.7.2. Choice of Statistical Software

Software To estimate the model, bootstrap the estimates, and obtain the criteria for assessing the measurement and the structural components, the study will use SmartPLS 4 (Ringle et al., 2024). SmartPLS 4 is a popular PLS–SEM software that encompasses the model assessment functions necessary for current practices in scholarly research (Cheah, 2024).

3.7.3. Measurement Model

Measurement model assessment Indicator reliability will be assessed via the outer loadings. Internal consistency will be assessed using Cronbach’s alpha and composite reliability.

Convergent validity will be assessed using the average variance extracted. The heterotrait–monotrait ratio will be used to test discriminant validity as it is a recommended test for discriminant validity in the context of variance-based SEM (Henseler et al., 2015).

3.7.4. Structural Model

Structural model assessment Collinearity will be assessed with the variance inflation factors. Path estimation and their significance will be computed using bootstrapping with a large number of resamples. R^2 will be given to assess the endogenous constructs and f^2 as a measure to evaluate the practical significance (Cohen, 1992). If applicable, the Q^2 -based predictions are assessed with the PLS–SEM specific functionality (Hair et al., 2017; Hair & Alamer, 2022).

3.7.5. Control of Common Method Bias

How we will reduce any one typical source of error. As the data will be collected through a single source in this study, we will follow the guidelines for procedural and statistical remedies

to reduce common method bias. Procedural strategies entail guaranteeing respondent anonymity, minimizing evaluation apprehension, and enhancing item clarity. Statistical strategies to mitigate common method bias involve using specific collinearity VIF thresholds recommended by for the PLS-SEM context by (Kock, 2015).

4. Project Plan

4.1. Overview

Below is a Gantt Chart of my Project Plan:

5. Conclusion

By examining how citizens use Guyana's online government tools we were able to identify gaps in long-term participation especially on the GRA Padna App. Because continuous interaction with a government tool leads to real impact, a user temporarily using an app can negate what we expect to happen even when the tool is built well. Some reasons for this temporary usage include unclear benefits, frustration during usage, lack of confidence in the app's security or poor support. In the Guyanese context there is unequal internet availability, variable levels of tech literacy and varying levels of resources across the regions. Without addressing these contextual issues, plans with the intention of improving public service delivery will continue to be at risk of failure. With the goal of tackling these issues, the research utilizes a method rooted in theory, tailored to answer the question, what factors account for the low continued use of the GRA Padna app by Guyanese taxpayers. Instead of a qualitative exploration, we utilized a quantitative approach with numbers taking the center stage. Quantitative data was collected from Guyanese adults who used the Padna app. To analyze this data a snapshot style analysis was utilized mainly because it relates to the goal which involves examining how known ideas connect and judging which ideas weigh more in deciding ongoing use and early drop off. The

Expectation–Confirmation Model was utilized to track what happens after adoption. Constructs like routine behavior, peer pressure, support systems, along with confidence in the system and feelings of safety were pulled from UTAUT2. Data are collected through a structured questionnaire developed from tested instruments and are analyzed using partial least squares structural equation modelling. Using this approach, it examines the reliability and validity of the measures while assessing the relationship between the theoretical factors. Although the process is guided by strong methods, the outcome remains closely linked to real-world governance contexts. The findings are based on real-world application rather than only theoretical considerations. Previous studies suggest results before data are collected. This study is expected to identify key reasons for contributing to stalled usage by distinguishing between emotional factors such as user fulfilment and experience validation from functional factors such as perceived value and effectiveness. In addition to trust to perceived security, environmental factors such as peer influence and ease of access play a major role. The findings from this research are expected to help GRA retain users on PADNA, lower drop off rates and improve the platform's dependability. Extending beyond Padna, these findings can support other public digital platforms in Guyana that face similar challenges. Currently, the research is limited to a single point in time and relies mainly on self-reports. However, future research could monitor users' overtime and assess changes in views especially in tax periods. Future studies can also analyze real usage data with permission instead of only depending on survey results. Future studies may also investigate user differences by age, income and location and compare the results to other government platforms in Guyana to verify if the problem is widespread. The next phase can also include enhancing survey tools, getting approval, collecting and analyzing data while

producing recommendations for GRA. Overall, the objective of this study is to examine the reasons why users leave the platform and how to promote long-term usage.
